Methodology: The survey used a multi-stage cluster sampling design. The first stage was the selection of enumeration areas (EAs) from a list of all EAs in the country. The second stage was the selection of households within the chosen EAs. The third stage was the selection of individuals within the chosen households. The survey included a physical examination component where height and weight were measured for a subset of the sample. The BMI was calculated as weight in kilograms divided by height in meters squared (kg/m^2). The survey also included a dietary assessment component where individuals were asked about their usual diet and food intake.
